## i Use the conflicted package (<http://conflicted.r-lib.org/>) to force all conflicts to become errors
```

```
library(dplyr)
```

Web Scraping

In this assignment, your task is to scrape some information from Wikipedia. We start with the following page about Grand Boulevard, a Chicago Community Area.

https://en.wikipedia.org/wiki/Grand_Boulevard,_Chicago

The ultimate goal is to gather the table "Historical population" and convert it to a `data.frame`.

As a first step, read in the html page as an R object. Extract the tables from this object (using the `rvest` package) and save the result as a new object. Follow the instructions if there is an error. Use `str()` on this new object -- it should be a list. Try to find the position of the "Historical population" in this list since we need it in the next step.

```
url <- read_html("https://en.wikipedia.org/wiki/Grand_Boulevard,_Chicago")
table_list <- html_nodes(url, xpath = '//table')
#table_list <- html_nodes(url, xpath = '//*[@id="mw-content-text"]/div[1]/table[2]')
#table <- html_table(table_list)
str(table_list)
```

```
## List of 7
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  $ :List of 2
##   ..$ node:<externalptr>
##   ..$ doc :<externalptr>
##   ..- attr(*, "class")= chr "xml_node"
##  - attr(*, "class")= chr "xml_nodeset"
```

Extract the "Historical population" table from the list and save it as another object. You can use subsetting via [[...]] to extract pieces from a list. Print the result.

```
pop <- table_list[[2]]
pop
```

```
## {html_node}
## <table class="us-census-pop us-census-pop-left">
## [1] <caption>Historical population</caption>
## [2] <tbody>\n<tr>\n<th scope="col">Census</th>\n<th scope="col"><abbr title=" ...
```

You will see that the table needs some additional formatting. We only want rows and columns with actual values (I called the table object pop).

```
pop <- html_table(pop)
pop <- pop %>%
  filter(row_number() <= n()-1)%>%
  select(c(1:2,4))
```

```
 pop <- pop[2:10, -3]
 pop
```

```
## # A tibble: 9 x 2
##    Census Pop.
##    <chr>  <chr>
## 1 1940    103,256
## 2 1950    114,557
## 3 1960    80,036
## 4 1970    80,166
## 5 1980    53,741
## 6 1990    35,897
## 7 2000    28,006
## 8 2010    21,929
## 9 2020    24,589
```

Expanding to More Pages

That's it for this page. However, we may want to repeat this process for other community areas. The Wikipedia page https://en.wikipedia.org/wiki/Grand_Boulevard,_Chicago has a section on "Places adjacent to Grand Boulevard, Chicago" at the bottom. Can you find the corresponding table in the list of tables that you created earlier? Extract this table as a new object.

```
adjacent_Chi <- table_list[[4]]
```

Then, grab the community areas east of Grand Boulevard and save them as a character vector. Print the result.

```
places_east <- html_table(adjacent_Chi)$X3
places_east <- places_east[-c(2,4)]
places_east
```

```
## [1] "Oakland, Chicago"   "Kenwood, Chicago"   "Hyde Park, Chicago"
```

We want to use this list to create a loop that extracts the population tables from the Wikipedia pages of these places. To make this work and build valid urls, we need to replace empty spaces in the character vector with underscores. This can be done with gsub(), or by hand. The resulting vector should look like this: "Oakland,_Chicago" "Kenwood,_Chicago" "Hyde_Park,_Chicago"

```
places_east <- gsub(pattern = " ", replacement = "_" , x = places_east)
places_east
```

```
## [1] "Oakland,_Chicago"   "Kenwood,_Chicago"   "Hyde_Park,_Chicago"
```

To prepare the loop, we also want to copy our pop table and rename it as pops. In the loop, we append this table by adding columns from the other community areas.

```
pops <- pop
```

Build a small loop to test whether you can build valid urls using the vector of places and pasting each element of it after https://en.wikipedia.org/wiki/ in a for loop. Calling url shows the last url of this loop, which should be https://en.wikipedia.org/wiki/Hyde_Park,_Chicago.

```
for(i in 1:length(places_east)) {
  url <- paste0("https://en.wikipedia.org/wiki/" , places_east[i])
 }
url
```

```
## [1] "https://en.wikipedia.org/wiki/Hyde_Park,_Chicago"
```

Finally, extend the loop and add the code that is needed to grab the population tables from each page. Add columns to the original table `pops` using `cbind()`.

```
for(i in 1:length(places_east)) {
  url <- paste0("https://en.wikipedia.org/wiki/" , places_east[i])
  url <- read_html("https://en.wikipedia.org/wiki/Grand_Boulevard,_Chicago")
  table_list <- html_nodes(url, xpath = '//table')
  hpset <- table_list[[2]]
  hpset <- html_table(hpset)
  hpset <- hpset %>%
    filter(row_number() <= n()-1)%>%
    select(c(1:2,4))
  pops = hpset[2:10, -3] %>% cbind(pops, .)
}

pops
```

```
##    Census     Pop. Census     Pop. Census     Pop. Census     Pop.
## 1    1940 103,256    1940 103,256    1940 103,256    1940 103,256
## 2    1950 114,557    1950 114,557    1950 114,557    1950 114,557
## 3    1960  80,036    1960  80,036    1960  80,036    1960  80,036
## 4    1970  80,166    1970  80,166    1970  80,166    1970  80,166
## 5    1980  53,741    1980  53,741    1980  53,741    1980  53,741
## 6    1990  35,897    1990  35,897    1990  35,897    1990  35,897
## 7    2000  28,006    2000  28,006    2000  28,006    2000  28,006
## 8    2010  21,929    2010  21,929    2010  21,929    2010  21,929
## 9    2020  24,589    2020  24,589    2020  24,589    2020  24,589
```

Scraping and Analyzing Text Data

Suppose we wanted to take the actual text from the Wikipedia pages instead of just the information in the table. Our goal in this section is to extract the text from the body of the pages, then do some basic text cleaning and analysis.

First, scrape just the text without any of the information in the margins or headers. For example, for "Grand Boulevard", the text should start with, "**Grand Bouleavard** on the South Side of Chicago, Illinois, is one of the . . . ". Make sure all of the text is in one block by using something like the code below (I called my object `description`).

```
text <- html_nodes(url, xpath = '//p')
#text <- text[[2]]
text <- html_text(text)

# description <- description %>% paste(collapse = ' ')
```

Using a similar loop as in the last section, grab the descriptions of the various communities areas. Make a tibble with two columns: the name of the location and the text describing the location.

Let's clean the data using `tidytext`. If you have trouble with this section, see the example shown in https://www.tidytextmining.com/tidytext.html

```r
library(tidytext)
```

Create tokens using `unnest_tokens`. Make sure the data is in one-token-per-row format. Remove any stop words within the data. What are the most common words used overall?

Plot the most common words within each location. What are some of the similarities between the locations? What are some of the differences?
